### Solution Architecture:

Solution architecture for this project connects the Incident-management problem with ServiceNow client-side controls. The architecture defines the structure and behavior of the Incident interface, the configuration components used to enforce business rules, and the validation flow before an Incident record is submitted.

The solution uses the Incident form and list as the user interaction layer. UI Policies and UI Policy Actions control conditional field behavior, while onChange, onSubmit, and onCellEdit Client Scripts provide automatic updates, save-time validation, and list-edit restrictions. The resulting behavior helps ensure complete and consistent Incident data.

### Goals of the Solution Architecture

- Find a ServiceNow configuration-based solution for inconsistent and incomplete Incident data entry.
- Describe the structure and behavior of the Incident interface controls.
- Define the client-side components used to implement the project requirements.
- Provide a clear flow from user action to validation and controlled Incident record updates.

### Example – Architecture and Data Flow of the Incident Solution
